

Calculate Age from Birth Year in Python

A beginner-friendly introduction to user input, math, and output in Python.

What This Program Does

→ Ask

Prompts the user to enter their birth year

→ Calculate

Subtracts the birth year from 2026 to find the age

→ Display

Prints the result clearly on the screen

The Code

```
birth_year = int(input("Enter your birth year: "))  
age = 2026 - birth_year  
print("Your age is:", age)
```

Just 3 lines — that's all it takes to build this program in Python.

Breaking Down Line 1

```
birth_year = int(input("Enter your birth year: "))
```

input()

Pauses the program and waits for the user to type something

int()

Converts the typed text into a whole number the computer can use for math

birth_year =

Stores the number in a container called a **variable**

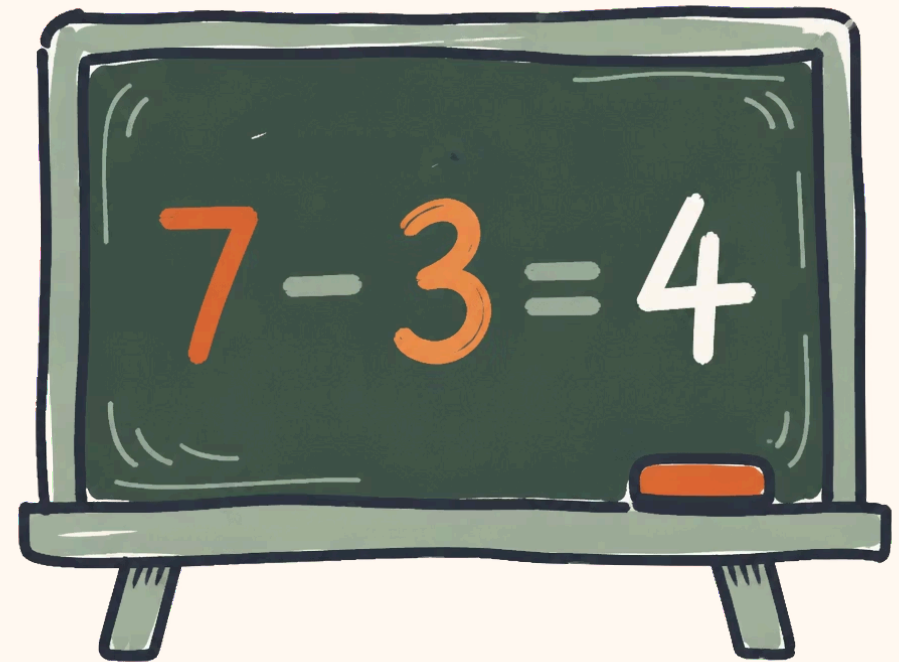

Breaking Down Line 2

The Math

```
age = 2026 - birth_year
```

Subtracts the birth year from 2026 and saves the result in a new variable called **age**.

❏ Example: $2026 - 2000 = 26$

Breaking Down Line 3

```
print("Your age is:", age)
```

print()

Displays text and values on the screen for the user to read

The Label

"Your age is:" — a fixed message that always appears as written

The Result

Output example: *Your age is: 26*
